Botulism

Communicable

Virulent

Health Protection and Promotion Act:
O. Reg. 135/18 (Designation of Diseases)

1.0 Aetiologic Agent

Botulinum toxin is produced by *Clostridium botulinum* (*C. botulinum*), which is a Gram positive, spore-forming obligate anaerobic bacillus.¹

2.0 Case Definition

2.1 Surveillance Case Definition

See Appendix B

2.2 Outbreak Case Definition

A single case of botulism, other than infant botulism, should be managed as if it was an outbreak (see 6.5 Management of Outbreaks). A single case of infant botulism does not need to be managed as such and should be managed as a sporadic case of botulism (see 6.3 Management of Cases). However, two or more cases of infant botulism should be managed as an outbreak.

Outbreak case definitions are established to reflect the disease and circumstances of the outbreak under investigation. Confirmed outbreak cases must at a minimum meet the criteria specified for the provincial surveillance confirmed case classification. Consideration should also be given to the following when establishing outbreak case definitions:

- Clinical and/or epidemiological criteria;
- The time frame for occurrence (i.e., increase in endemic rate);
- A geographic location(s) or place(s) where cases live or became ill/exposed;
- Special attributes of case(s) (e.g., age, underlying conditions); and
- Further typing (e.g. neurotoxin subtype) as appropriate, which may be used to support linkage.

Cases may be classified by levels of probability (i.e. confirmed, probable and/or suspect).
3.0 Identification

3.1 Clinical Presentation

For information on clinical presentations in case investigations refer to the Ministry of Health and Long-Term Care’s (ministry) document Botulism – Guide for Healthcare Professionals (Version: March, 2017).

There are three main forms of botulism depending on the mode of transmission: foodborne, wound, and intestinal (infant and adult) botulism. All forms cause flaccid paralysis as a result from the botulinum neurotoxin.

Foodborne botulism is a severe intoxication resulting from ingestion of preformed toxin present in contaminated food. Most individuals develop the following symptoms: nausea, vomiting, diarrhea, constipation, fatigue, weakness, dizziness, blurred or double vision, dysphasia, and dry mouth may occur. Acute bilateral cranial nerve impairment and descending weakness or paralysis characterize the illness. Most people recover if diagnosed and treated quickly, but recovery may take months and some have residual weakness.

Wound botulism occurs when spores penetrate an open wound and produce the toxin in an anaerobic environment. Symptoms are similar to food borne botulism but may take up to two weeks to appear.

Intestinal (infant and adult colonization) botulism occurs following spore ingestion, subsequent outgrowth and in-vivo toxin production in the intestine; it affects children under one year but can also affect adults who have altered intestinal microflora because of antimicrobial use or because of bowel abnormalities. Clinical symptoms in infants include constipation, loss of appetite, poor suck, weakness, lethargy, altered cry, and a striking loss of head control known as “floppy head”.

Other forms of botulism include iatrogenic and inhalational. Iatrogenic botulism is caused by accidental overdose of botulinum toxin that is injected for cosmetic or other indications (e.g. neuromuscular disorders). Inhalational botulism is the result of inhaling aerosolized botulinum neurotoxin. Clinical manifestations are similar to other forms of botulism.

3.2 Diagnosis

See Appendix B for diagnostic criteria relevant to the Case Definition.

Identification of organisms in suspected food is helpful but not diagnostic because C. botulinum spores are ubiquitous. The diagnosis may be accepted in a person with the clinical syndrome who had consumed food incriminated in a laboratory-confirmed case.

Diagnosis is made in collaboration with Health Canada’s National Botulism Reference Service in Ottawa. The Botulism Reference Service office can be reached during working hours at 613-957-0902 or after-hours at 613-296-1139.

4.0 Epidemiology

4.1 Occurrence

Botulism is a rare disease in Ontario with five cases reported from 2013 to 2017*. Please refer to Public Health Ontario’s (PHO) Reportable Disease Trends in Ontario reporting tool and other reports for the most up-to-date information on infectious disease trends in Ontario.4,5

http://www.publichealthontario.ca/en/DataAndAnalytics/Pages/DataReports.aspx

4.2 Reservoir

C. botulinum spores are ubiquitous in soil worldwide; are frequently recovered from agricultural products, including honey and produce, and are also found in dust, soil, marine sediments, and in the intestinal tract of animals, including fish.1

4.3 Modes of Transmission

Foodborne botulism is transmitted by the ingestion of improperly prepared, stored or cooked food containing the toxin. The foods most often implicated are lightly preserved foods (such as smoked and salted fish) and in inadequately processed, home-preserved foods (including fruits, vegetables, and herbs in oil) that are low in sugar, salt, and acid.1

Wound botulism results from contamination of traumatized tissue by C. botulinum found in soil that grows in the wound and produces toxin.1 The majority of wound botulism occurs among injection drug users who subcutaneously inject illicit drugs that may be contaminated with C. botulinum spores.6

Intestinal (infant and adult) botulism is typically associated with the ingestion of spores that germinate and produce toxin in the colon that may be present in sources including: soil, dust, unpasteurized honey, and peanut butter.1

4.4 Incubation Period

In foodborne botulism neurological symptoms usually appear within 12 to 36 hours after ingestion of contaminated food, or up to several days after eating contaminated food. The shorter the incubation period, the more severe the disease and the higher the case-fatality rate.1,3

* Data included in the epidemiology summary are from January 1, 2013 to December 31, 2017. Data were extracted from Query on February 7, 2018 and therefore are considered preliminary.
For wound botulism, the incubation period is generally 4 to 14 days.\textsuperscript{1} The incubation period of intestinal botulism in infants is estimated to be up to 30 days, but for adults in unknown since the precise time of spore ingestion often cannot be determined.\textsuperscript{1}

4.5 Period of Communicability

No instance of secondary person-to-person transmission has been documented despite excretion of \textit{C. botulinum} toxin and organisms in the feces of intestinal (infant) and foodborne botulism cases.\textsuperscript{1} People with foodborne botulism typically excrete the toxin for shorter periods.\textsuperscript{1}

4.6 Host Susceptibility and Resistance

Susceptibility is general. Adults with anatomical or functional bowel abnormalities leading to altered intestinal flora (unintentionally altered by antibiotic treatment for other purposes) may be predisposed to intestinal botulism.\textsuperscript{1} Injection drug users are more susceptible to wound botulism.\textsuperscript{6}

5.0 Reporting Requirements

The minimum data elements to be reported for each case are specified in the following sources:

- Ontario Regulation 569 (Reports) under the \textit{Health Protection and Promotion Act} (HPPA);\textsuperscript{7}
- The iPHIS User Guides published by PHO; and
- Bulletins and directives issued by PHO.

6.0 Prevention and Control Measures

6.1 Personal Prevention Measures

\begin{itemize}
  \item Foodborne botulism:
    \begin{itemize}
      \item Practice safe food preparation and canning processes. For more information on safe home canning practices, please see Health Canada's website 'Food Safety Tips for Home Canning' \url{http://healthycanadians.gc.ca/eating-nutrition/safety-salubrite/food-canning-conserve-aliment-eng.php#a3}
      \item Refrigerate foods stored in oil (e.g. oils infused with garlic, herbs, and vegetables).
      \item Follow storage and shelf-life recommendations on food labels.
      \item Avoid consumption of canned or bottled foods that are dented, leaking or have bulging ends, or it is suspected they have been tampered with.\textsuperscript{8}
    \end{itemize}
\end{itemize}
Wound botulism:
- Avoid injection of illicit drugs
- Seek prompt medical attention for infected wounds.6

Infant botulism:
- Do not feed honey to infants less than one year of age.

### 6.2 Infection Prevention and Control Strategies
Refer to PHO’s website at [www.publichealthontario.ca](http://www.publichealthontario.ca) to search for the most up-to-date best practices on Infection Prevention and Control (IPAC).

### 6.3 Management of Cases
In addition to the responsibilities set out in the requirements in the *Infectious Disease Protocol, 2018,* (or as current), the Board shall investigate cases and suspected exposures in collaboration with the attending physician, PHO, the Botulism Reference Service (BRS) in Ottawa, as well as with the Public Health Agency of Canada (PHAC). If required, notification of the Canadian Food Inspection Agency (CFIA) will be made in collaboration with the PHO and PHAC, as well as decisions for any other communication and or notification that are required.

Additional case follow-up may include:
- The collection of food histories 2-3 days prior to symptom onset (including: when consumed, where obtained)
- History of other risk behaviours or exposures (e.g. site and date of injury, illicit drug use)
- The collection of food samples of suspected sources of intoxication for laboratory analysis using appropriate media, sampling techniques and routine practices for the handling of suspect food
- Coordinate food and clinical specimen collection (as appropriate), and communicate with the Botulism Reference Service in Ottawa at tel. # 613-957-0902 or after hours at 613-296-1139

### Treatment:
Immediate medical treatment is required; do not await laboratory confirmation. Botulinum Antitoxin (BAT) can be accessed through the Population and Public Health Division - Ministry of Health and Long-Term Care (ministry) during business hours by calling 416-327-7392. After-hours and on weekends and holidays please call the ministry’s Health Care Provider Hotline at 1-866-212-2272 and request to speak to the Population and Public Health Division staff on call.

Treatment of infant botulism requires Botulism Immune Globulin, Intravenous (BIG-IV) or BabyBIG ®. This can only be obtained through Health Canada’s Special Access Program (SAP).

For more information on placing a request for BAT or BabyBIG ®refer to the MOHLTC document “Botulism – Guide for Healthcare Professionals” *(Version: March 2017).*
6.4 Management of Contacts (foodborne botulism only)

Contacts are managed as part of the outbreak as per the Infectious Disease Protocol, 2018 (or as current) for people who are known to have eaten contaminated food or who have shared a likely exposure should be advised to consult with their health care provider for assessment and/or treatment.

6.5 Management of Outbreaks

Please refer to the Infectious Disease Protocol, 2018, (or current) for steps in managing outbreaks. Given the severity and rarity of botulism, one case of botulism (or two or more cases of infant botulism) should be treated as if it was an outbreak and should be managed with great urgency (with the exception of a single case of infant botulism, which should be managed as a sporadic case of botulism). Foodborne botulism outbreaks should be managed according to the Ontario’s Foodborne Illness Outbreak Response Protocol (ON-FIORP): http://www.health.gov.on.ca/en/pro/programs/publichealth/enviro/ and will include the Botulism Reference Service and the attending physician(s) in order to handle the unique laboratory testing needs and urgency of a botulism outbreak.
