Appendix A: Disease-Specific Chapters

Chapter: Clostridium difficile Infection (CDI) outbreaks in public hospitals

[Known as Clostridium difficile associated disease (CDAD) in the regulations under the HPPA]

Effective: February 2019
Clostridium difficile Infection (CDI) outbreaks in public hospitals

- Communicable
- Virulent

Health Protection and Promotion Act:
O. Reg. 135/18 (Designation of Diseases)

1.0 Aetiologic Agent

Clostridium difficile (C. difficile) is a gram-positive, spore-forming, anaerobic bacillus. It is widely distributed in the environment and colonizes up to 3-5% of adults without causing symptoms. Some strains can produce two toxins that are responsible for diarrhea: toxin A and toxin B.¹

2.0 Case Definition

2.1 Surveillance Case Definition

Refer to Appendix B for Case Definitions.

2.2 Outbreak Case Definition

The outbreak case definition varies with the outbreak under investigation. Please refer to the Infectious Diseases Protocol, 2018 (or as current) for guidance in developing an outbreak case definition as needed.

The outbreak case definitions are established to reflect the disease and circumstances of the outbreak under investigation. The outbreak case definitions should be developed for each individual outbreak based on its characteristics, reviewed during the course of the outbreak, and modified if necessary, to ensure that the majority of cases are captured by the definition. The case definitions should be created in consideration of the outbreak definitions.

Outbreak cases may be classified by levels of probability (i.e. confirmed and/or probable).

Please also see Annex C of the Provincial Infectious Diseases Advisory Committee (PIDAC)’s Routine Practices and Additional Precautions in All Health Care Settings.¹

3.0 Identification

3.1 Clinical Presentation
Symptoms of *C. difficile* infection (CDI) include:\(^2\)

- Diarrhea (as defined in Appendix B);
- Fever;
- Loss of appetite;
- Nausea; and
- Abdominal pain or tenderness.

Complications include dehydration and colitis,\(^2\) and may also lead to life threatening systemic toxicity requiring surgical intervention and may also lead to death.\(^1,2\)

Recurrence of CDI is common and occurs in about 30% of cases.\(^1\)

### 3.2 Diagnosis

See Appendix B for diagnostic criteria relevant to the Case Definitions.

For additional information, please consult Public Health Ontario’s (PHO) testing information on *Clostridium difficile*.\(^3\)

### 4.0 Epidemiology

#### 4.1 Occurrence

*C. difficile* is the most frequent cause of infectious diarrhea in health care facilities in Canada.\(^4\) Outbreaks in Canada, the United States, and Europe have been associated with a hypervirulent epidemic strain referred to as the NAP1/BI/027 strain. Characteristics of this strain include the presence of a binary toxin; increased resistance to clindamycin and the fluoroquinolone class of antibiotics; and an increased likelihood of a serious illness.\(^1\)

Between 2013 and 2017, an average of 2,661 cases (confirmed and probable) of CDI has been reported per year in Ontario.\(^*\)

Rates of CDI associated with reporting facilities have decreased 27%, from 3.0 per 10,000 patient days in 2013 to 2.2 per 10,000 patient days in 2017.

Please refer to PHO’s Reportable Disease Trends in Ontario reporting tool and other reports for the most up-to-date information on infectious disease trends in Ontario.

[http://www.publichealthontario.ca/en/DataAndAnalytics/Pages/DataReports.aspx](http://www.publichealthontario.ca/en/DataAndAnalytics/Pages/DataReports.aspx)

For additional national and international epidemiological information, please refer to the Public Health Agency of Canada and the World Health Organization.

\(^*\) Data included in the epidemiological summary are from January 1, 2013 to December 31, 2017. Data were extracted from Query on February 7, 2018 and therefore are considered preliminary.
4.2 Reservoir

*C. difficile* bacteria are found in feces of humans.\textsuperscript{4}

4.3 Modes of Transmission

*C. difficile* is widely distributed in the environment. It produces spores that survive for longer periods of time and are resistant to destruction by environmental factors (e.g. temperature, humidity), including standard cleaning agents.\textsuperscript{5} In an effort to protect itself from undesirable environmental conditions, it assumes its spore form.

*C. difficile* is spread through the fecal-oral route of transmission.\textsuperscript{4} *C. difficile* can be acquired in both hospital and community settings.\textsuperscript{5} *C. difficile* can be transmitted and/or acquired by patients through contact with contaminated surfaces (including both vegetative cells and spores).

CDI may occur when antibiotics kill normal bowel bacteria and allow the *C. difficile* to grow. When *C. difficile* grows, it may produce toxins, which can damage the bowel and may cause diarrhea.\textsuperscript{4}

4.4 Incubation Period

The incubation period of *C. difficile* following acquisition has not been clearly defined. Studies have determined that onset of infection can occur within 48 hours after exposure and up to 3 months post exposure.\textsuperscript{6,7}

4.5 Period of Communicability

Precise period of communicability is unknown; it may vary depending on the amount of toxin in the stool, which can vary from very small to large spores and are very difficult to eliminate from surfaces and objects. Cytotoxins may persist in stool for weeks.\textsuperscript{1}

4.6 Risk Factors for Acquisition of CDI

Risk Factors associated with CDI include:\textsuperscript{1}

- a history of antibiotic usage, particularly broad spectrum antibiotics that affect the normal gut bacterial flora, such as fluoroquinolones;
- immunosuppressive therapy post-transplant;
- proton pump inhibitors;
- bowel disease and bowel surgery;
- chemotherapy; and/or
- hospitalization.

Additional risk factors that predispose some people to develop more severe disease include:\textsuperscript{1}

- history of CDI;
- increased age;
- immunosuppressive therapy;
• recent surgery; and/or
• CDI with the hypervirulent strain of C. difficile.

5.0 Reporting Requirements
As per Requirement #3 of the “Reporting of Infectious Diseases” section of the Infectious Diseases Protocol, 2018 (or as current), the minimum data elements to be reported for each case are specified in the following:

- Ontario Regulation 569 (Reports) under the Health Protection and Promotion Act (HPPA);8
- The iPHIS User Guides published by PHO; and
- Bulletins and directives issued by PHO.

6.0 Prevention and Control Measures

6.1 Personal Prevention Measures
Effective hand hygiene is essential to limit the spread of C. difficile. Other infection prevention and control strategies, including, but not limited to, education for staff, patients, visitors/families may be used.1

Messaging to visitors should be written in clear language and include the following:

- What is CDI and what the visitor’s risk of acquiring it is;
- How to properly clean their hands (and its importance);
- When personal protective equipment is needed and how to put on and take off;
- Measures to take when providing direct care to the patient/or having significant contact with the patient’s environment (i.e. wear gown and gloves);
- Instructions to only use visitor washrooms and where these are located; and
- Instructions to visit their significant other in isolation last if they are visiting more than one person in the hospital.

6.2 Infection Prevention and Control Strategies
Prevention Strategies in institutions include:1

- early identification and testing of patients with symptoms;
- empowering front-line staff to institute additional precautions at onset of symptoms; and
- daily surveillance reporting to Infection Prevention and Control program staff.

In addition to Routine Practices, Contact Precautions should be initiated by any regulated health care provider (e.g., physician, nurse) at onset of diarrhea and prior to receipt of C. difficile test results.

More detailed information is available in the PIDAC’s Annex C: Testing, Surveillance and Management of Clostridium difficile.1
6.3 Management of Cases

In addition to the requirements set out in the Requirement #2 of the “Management of Infectious Diseases – Sporadic Cases” and “Investigation and Management of Infectious Diseases Outbreaks” sections of the *Infectious Diseases Protocol, 2018* (or as current), the board of health may be requested to provide guidance to manage cases. Individual cases should be managed as per individual facility protocols. Facilities developing protocols may refer to the Roles and Responsibilities of Hospitals and Public Health Units in CDI Reporting and Outbreak Management, 2014 (or as current) and the PIDAC’s Annex C: Testing, Surveillance and Management of Clostridium difficile.¹,⁹

6.4 Management of Contacts

Not applicable.

6.5 Management of Outbreaks

Provide public health support to health care facilities in the management of outbreaks or clusters in order to identify the source of illness and manage the outbreak as per the *Infectious Diseases Protocol, 2018* (or as current) and Roles and Responsibilities of Hospitals and Public Health Units in CDI Reporting and Outbreak Management, 2014 (or as current), See Appendix B for the CPE outbreak definition.⁹ PHO’s Infection Control Resource Teams (ICRTs) can provide Infection Control expertise and support in the event of an outbreak.

The criteria for declaring an outbreak over should be determined collaboratively by the facility and the local public health unit as part of the outbreak management team process.

Factors to consider in declaring an outbreak over should include:

- Control measures have been implemented and validated through an audit process.
- There has been a return to unit/ ward or facility baseline for nosocomial CDI. For a facility-wide outbreak, this should be a minimum period of one month.
- Reservoir of colonized patients/ residents in the facility has been discharged.
- Facility’s past experience with CDI outbreaks demonstrates ability to bring them under control.
